

1.0 Introduction

The Builder Connect Application (Henceforth referred to simply as the "Application") is a product that Kenna provides to its clients at BASF Construction North America. It is a comprehensive suite of tools and solutions that enable BASF marketing professionals to make better-informed decisions and to better engage with their customers. Among its many features, the Application derives much value from its Reporting Utilities. Easily accessible via the top navigation bar, the "Reports" sections of the Application shows various reports generated from the data the Application has collected from its users.

Because the Application accommodates for different classes of users, the Reports section likewise will also show different reports depending on the specific roles and responsibilities of the current user. Here, the author would like to highlight the Management Reports. Accessed via the "Management Reports" tab in the sliding side navigation bar (Figure 1.0), these reports are an indispensable source of information for users in an organizational role.

Figure 1.0: Navigating to the Management Reports

A key component of the Management Reports is the filters panel (Figure 1.1). This panel provides a number of controls which management users can use in order to fine-tune the dataset the reports draw from. This unassuming feature is a crucial component of the Management Reports because it provides the user with greater depth into their data, giving them multiple perspectives and, therefore, allowing them to optimize their future strategy. These filters are the focus of discussions in this report.

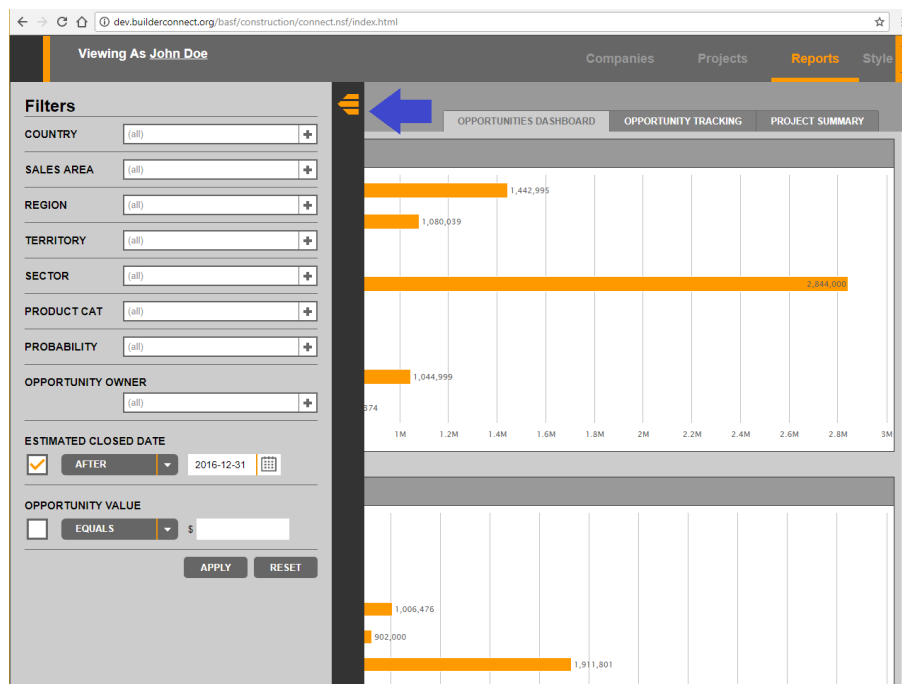

Figure 1.1: The Management Report Filters

When this author was tasked with adding a number of newer controls to the Management Report Filters, he had to examine the existing infrastructure to understand how the Filters worked. In doing so, the author discovered several points of weakness in the existing framework which created unnecessary complications and made future maintenance and expansion difficult. If steps are not taken to correct these shortcomings, then the development of not just the filters, but the Reports sections as a whole, is likely to be hindered. Thus, the purpose of this report is to

provide the first step in the process of improvement by describing and analyzing the deficiencies in the existing infrastructure.

2.0 – Analysis

2.1 – The Existing Infrastructure

For the aforementioned purpose, the author now finds it helpful to provide an overview of the old system.

In brief, the Management Report Filters work as follows:

1. When the Application first starts, a function called `init_reports()` is called.
2. This function creates a *closure*, within which a variable, `mgmt_report_filters`, is defined.
This variable keeps track of the state of the controls in the filters panel.
3. When the user interacts with the filters panel, the selections and inputs they give are, for the most part, registered and stored in `mgmt_report_filters`.
4. When the user clicks on the "Apply" button in the filters panel, the contents of `mgmt_report_filters` is copied over to a "mirror" Object in the *closure* of the `initReport()` function.
5. This mirror Object is *stringified* and inserted into the header of various XMLHttpRequests (Performed via `$.ajax()`), thus sending the filter information to the backend and ensuring that the response returned is filtered.

Having outlined the system, the following sections will dive into the system in greater depth, with an emphasis on highlighting its weaknesses. Two things, however, must be noted before continuing. First, without exception, all subsequent code to be shown in this report comes from

the file `reports.js`. Second, in all code shown, the appearance of the sequence of characters `/* ... */` is to denote code omitted for the purpose of keeping this report short and concise.

2.2 – An Inconsistent System

The first issue in the implementation of the Management Report Filters is the many inconsistencies it has both within itself and with other parts of the application. Here, the most concerning of these inconsistencies will be addressed.

To begin, the author would like to draw the reader's attention to another filters panel found within the Application. The Project List Filters (Figure 2.0) provides several filter controls which the user can use in order to find the projects they need.

The screenshot shows a web application interface for viewing project lists. The top navigation bar includes 'Companies', 'Projects' (highlighted), 'Reports', and 'Style'. The user is logged in as 'John Doe'. The left sidebar contains a 'Filters' section with a 'SELECT A FILTER' dropdown. Under 'Global Filters', there are 'CMD Project Leads' and 'IIR Project Leads'. Under 'Project Opportunity Filters', there are sections for 'PROBABILITY', 'OPPORTUNITY VALUE', 'ESTIMATED CLOSED DATE', 'PRODUCT CATEGORY', and 'SPECIFICATION', each with a checkbox and a search input. The main area displays a table of project data with columns: COUNTY, STATE, PRODUCT CATEGORY, SECTOR, PROBABILITY, OPPORTUNITY VALUE, and ESTIMATED CLOSE DATE. The table contains 10 rows of project data. At the bottom of the table, there is a pagination control showing '1 of 3'.

COUNTY, STATE	PRODUCT CATEGORY	SECTOR	PROBABILITY	OPPORTUNITY VALUE	ESTIMATED CLOSE DATE
Springs, NC	High Performance Concrete		Active - Low 25% Probability	\$7,777	Aug 22, 2017
Mon, Wilson,	Concrete Repair			\$10,000	Jul 18, 2017
ndria, VA	Surface Treatments	Parking	Active - Won	\$2,500,000	Nov 09, 2016
ach, MB	Master Seal AWB			\$500	Aug 10, 2016
George,	Concrete Repair		Active - Low 25% Probability	\$56	Jul 20, 2016
McMurray,	Concrete Repair		Active - Medium 60% Probability	\$12,133	Dec 15, 2015
otte, NC	Joint Sealants		Active - High 85% Probability	\$500,000	Nov 30, 2015
gami, ON	PF-Epoxy		Active - High 85% Probability	\$1,000	Nov 30, 2015
au, ON	Concrete Repair		Active - Medium 60% Probability	\$200	Nov 30, 2015
gami, ON	Surface Treatments		Active - Medium 60% Probability	\$50	Nov 28, 2015
gami, ON	Wall Coatings		Active - Medium 60% Probability	\$400,000	Nov 25, 2015
AL	Concrete Strengthening	C & I Flooring	Active - Low 25% Probability	\$789,000	
on, Boone,	Flooring Surfaces			\$10,000	

Figure 2.0: The Project List Filters

Several filter controls between the two filter panels are very much similar, if not exactly the same. Take, for example, the "Probability" filter control. In both filter panels, a click on the little white box with the "plus" symbol will open an overlay. The user can then make their selection in the overlay, click "Save," and see their selection show up in the box (Figures 2.1 to 2.3).

The screenshot shows a web application interface for viewing project opportunities. On the left is a 'Filters' panel with sections for 'Global Filters' (CMD Project Leads, IIR Project Leads) and 'Project Opportunity Filters'. The 'Project Opportunity Filters' section includes controls for 'PROBABILITY', 'OPPORTUNITY VALUE', 'ESTIMATED CLOSED DATE', 'PRODUCT CATEGORY', and 'SPECIFICATION'. A blue arrow points to a small white box with a plus symbol in the 'PROBABILITY' filter section. On the right is a table of project opportunities with columns: COUNTY, STATE, PRODUCT CATEGORY, SECTOR, PROBABILITY, OPPORTUNITY VALUE, and ESTIMATED CLOSE DATE. The table contains 12 rows of data. At the bottom of the table is a pagination control showing '1 of 3'.

COUNTY, STATE	PRODUCT CATEGORY	SECTOR	PROBABILITY	OPPORTUNITY VALUE	ESTIMATED CLOSE DATE
Springs, NC	High Performance Concrete		Active - Low 25% Probability	\$7,777	Aug 22, 2017
Wilson, NC	Concrete Repair			\$10,000	Jul 18, 2017
Andria, VA	Surface Treatments	Parking	Active - Won	\$2,500,000	Nov 09, 2016
Bach, MB	Master Seal AWB			\$500	Aug 10, 2016
George, NC	Concrete Repair		Active - Low 25% Probability	\$56	Jul 20, 2016
McMurray, NC	Concrete Repair		Active - Medium 60% Probability	\$12,133	Dec 15, 2015
otte, NC	Joint Sealants		Active - High 85% Probability	\$500,000	Nov 30, 2015
gami, ON	PF-Epoxy		Active - High 85% Probability	\$1,000	Nov 30, 2015
au, ON	Concrete Repair		Active - Medium 60% Probability	\$200	Nov 30, 2015
gami, ON	Surface Treatments		Active - Medium 60% Probability	\$50	Nov 28, 2015
gami, ON	Wall Coatings		Active - Medium 60% Probability	\$400,000	Nov 25, 2015
AL	Concrete Strengthening	C & I Flooring	Active - Low 25% Probability	\$789,000	
on, Boone, NC	Flooring Surfaces			\$10,000	

Figure 2.1: A click on the white box opens an overlay window

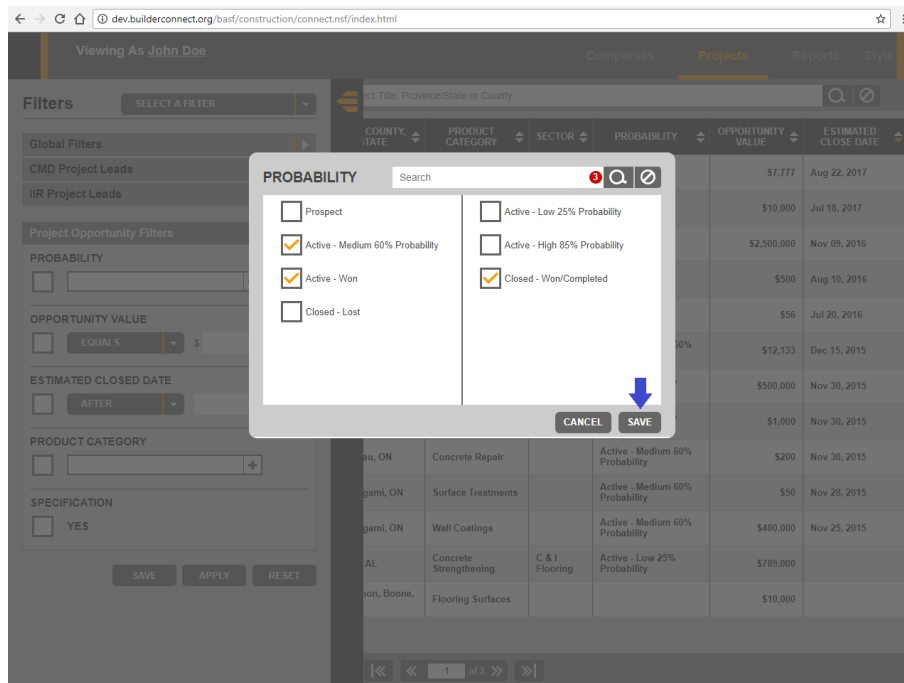

Figure 2.2: The user can make their selection and click “Save”

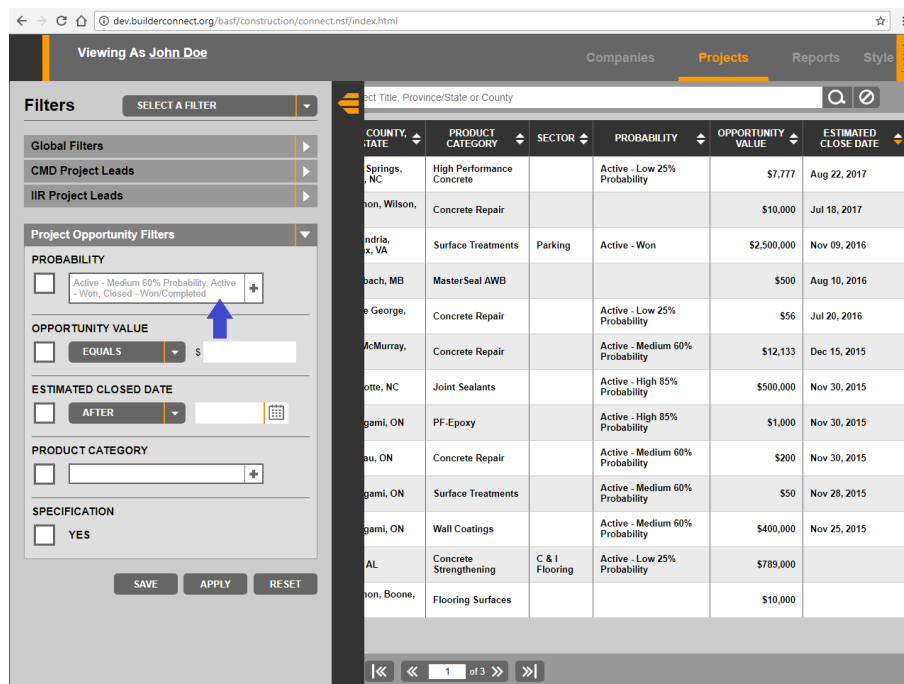

Figure 2.3: The user’s selection will be displayed in the box

As a result of their similarities in behaviour, one would expect that these two filters controls also share similar implementations. This, however, is not the case. The "Probability" filter in Project List Filters is implemented through what the author would like to call as the `$.list_filter()` strategy. The details of this strategy is too lengthy to be described here, but it is roughly as follows:

1. Choose a DOM element to be used as a list filter, initialize it by calling `$(selector).list_filter()`, where `selector` is a selector string that unique identifies the element.
2. As the user interacts with the element (e.g., Clicking on it to see an selection overlay), register the inputs given by the user and save them by calling `$(selector).list_filter('set_values', input)`, where `input` can be any value appropriate for representing the user's inputs.
3. When the filter information is needed (e.g., To be inserted into the URL of an XMLHttpRequest), get it by calling `$(selector).list_filter('get_values')`.

This strategy is widely adopted across the application for various filter controls in numerous different filters. But, for reasons unknown to the author, it is not used at all in the implementation of the Management Report Filters. A search of the term "list_filter" within `reports.js` yields no results.

Inconsistencies such as this scatter themselves across the implementation of the Management Report Filters and present challenges for future development as they force to developer to have to deal with multiple systems.

At this stage, one may be wondering how the "Probability" filter control and others like it are implemented in the Management Report Filters. Diving into this question reveals the next shortcoming of the Filters the author wishes to highlight.

2.3 – A Lack of Modularity

The DOM element used for the "Probability" filter control within the Management Report Filters has the attribute `data-role` set to the value `report-selection-overlay`. Figure 2.4, which is an excerpt from the `init_report()` function in `reports.js`, shows the attaching of a "click" event handler to this element.

```
// Note: body is a variable which holds document.body
body.on('click',
  '[data-role="report-selection-overlay"]'
+ ', [data-role="mgmt-report-selection-overlay"]'
+ ', [data-role="prjtrack-report-selection-overlay"]',
  function(e) {
    var $field = $(this);
    /* ... */
    var data_role = $field.attr('data-role');
    /* ... */
    if (data_role == "mgmt-report-selection-overlay") {
      /* ... */
    } else if (data_role == "prjtrack-report-selection-overlay") {
      /* ... */
    } else {
      /* ... */
    }

    getSelectionOverlayData(value_type, selected_filters, function(response) {
      /* ... */
      if (data_role == "mgmt-report-selection-overlay") {
        /* ... */
      } else if (data_role == "prjtrack-report-selection-overlay") {
        /* ... */
      } else {
        /* ... */
      }
      /* ... */
    });
  });
```

Figure 2.4: The "Click" event handler attached to the "Probability" filter control in Management Report Filters

This event handler, much of whose body has been intentionally omitted, will cause an overlay selection window to appear when the user clicks on the "Probability" filter control. Functionally speaking, this event handler achieves its purpose. But, design wise, it leaves a lot to be desired.

As one can see from the selector being passed to the `on()` function, this event handler is attached to all elements whose `data-role` attribute is one of the following: `report-selection-overlay`, `mgmt-report-selection-overlay` or `prjtrack-report-selection-overlay`. This shows that the behaviour of the "Probability" filter control is shared by many other elements. By attaching the same event handler to all of these elements, a good deal of code repetition is eliminated. Nevertheless, because of subtle differences between these three classes of elements, the function must make additional checks during runtime in order to alter its behaviour accordingly.

When used sparingly, this design is acceptable as it is an expedient and relatively straightforward solution. But a review of the `init_reports()` function shows that these types of checks are occurring over and over again. This design, in addition to being repetitive and hard to maintain, poses a major challenge to future growth and expansion. If more complex requirements and edge cases appear in the future, one can easily find themselves trapped in "If-Else Hell" with this design.

Speaking of code repetition, the author would like now to highlight the most glaring issue of the Management Report Filters' implementation. To do so, an analysis of exactly how the filters are applied is in order.

2.4 – A Senseless Repetition

As mentioned earlier, the `init_reports()` function creates a *closure* in which a variable, `mgmt_report_filters`, is defined (Figure 2.5).

```
var init_reports = (function() {  
    // Note: List_Map_Data is a wrapper class for the regular JavaScript  
    // Object. Instances of it can be treated like a regular Object.  
    var report_filters = new List_Map_Data();  
    var mgmt_report_filters = new List_Map_Data();  
    var prjtrack_report_filters = new List_Map_Data();  
  
    /* ... */  
  
    return function(body) {  
        /* ... */  
  
        body.on('click',  
            '[data-id="report-filter-apply"]'  
            + ', [data-id="mgmt-report-filter-apply"]',  
            function() {  
                /* ... */  
  
                setMgmtReportFilters(mgmt_report_filters);  
  
                /* ... */  
            });  
  
        /* ... */  
    }  
})();
```

Figure 2.5: The “init_reports()” function

This variable holds an object that will keep track of the Management Report Filters as the user interacts with its various controls. Figure 2.6 shows an example of what `mgmt_report_filters` might look like after certain filters have been selected.

When the user clicks on the "Apply" button, the "Click" event handler shown in the latter half of Figure 2.5 runs. This event handler will perform all of the steps necessary in applying the filters. The author has chosen to show the only part of this function relevant to the discussions at hand: the call to the function `setMgmtReportFilters()`.

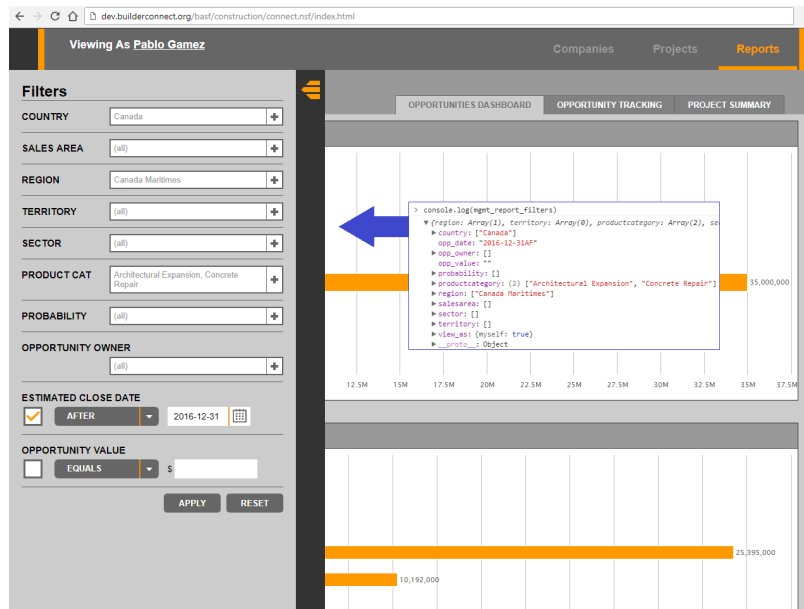

Figure 2.6: "mgmt_report_filters" changes to reflect the filters panel

This function has a global scope, thus allowing it to be invoked from anywhere throughout the program. However, its definition is found within the *closure* of another function, `initReport()` (Figure 2.7).

```
var initReport = ( function() {
    var report_filters = new List_Map_Data();
    var mgmt_report_filters = new List_Map_Data();
    var prjtrack_report_filters = new List_Map_Data();

    /* ... */

    setMgmtReportFilters = function(filters) {
        mgmt_report_filters.add('region', (filters.region || []).slice(0));
        mgmt_report_filters.add('territory', (filters.territory || []).slice(0));
        mgmt_report_filters.add('sector', (filters.sector || []).slice(0));
        mgmt_report_filters.add('productcategory', (filters.productcategory || []).slice(0));
        mgmt_report_filters.add('probability', (filters.probability || []).slice(0));
        mgmt_report_filters.add('opp_value', filters.opp_value);
        mgmt_report_filters.add('opp_date', filters.opp_date);
        mgmt_report_filters.add('opp_owner', (filters.opp_owner || []).slice(0));
        mgmt_report_filters.add('country', (filters.country || []).slice(0));
        mgmt_report_filters.add('salesarea', (filters.salesarea || []).slice(0));
    }

    /* ... */

    return function(options) {
        /* ... */
    }
})();
```

FIGURE 2.7: The “initReport()” function and definition for “setMgmtReportFilters()”

If the trio of variables at the beginning of the `initReport()` function seems familiar, it is because they are an exact replica of another trio of variables seen earlier in the `init_reports()` function. Furthermore, it is also clear from Figure 2.7 that the only purpose of the `setMgmtReportFilters()` function is to transfer data from its `filters` argument over to the `mgmt_report_filters` variables defined in the *closure* of `init_reports()`.

Thus, in Figure 2.5, when the "Click" event handler on the "Apply" button makes a call to `setMgmtReportFilters()`, all that happens is that the contents of the `mgmt_report_filters` variable in the `init_reports()` function is copied over to the `mgmt_report_filters` variable in the `initReport()` function.

Further examination reveals that the `setMgmtReportFilters()` function is only ever called from within the `init_reports()` function. Additionally, in all instances, the `mgmt_report_filters` variable (The one in the *closure* of `init_reports()`) is passed as the sole argument. This demonstrates that the only purpose of the `setMgmtReportFilters()` function is to "extend" the scope of the `mgmt_report_filters` variable to the `initReport()` function.

This is hardly a good design. With this repetition comes the need to maintain two distinct sets of objects. As one makes changes to the Management Report Filters in the future, they must ensure that the changes are reflected in both `init_reports()` and `initReport()`. Furthermore, if anything ever breaks, this repetition also means that there is one more point which the developer might have to check in their efforts to debug.

3.0 – Conclusions

The Management Report Filters are a crucial component of the Management Reports. While it is functionally stable, several weaknesses in its implementation and design create unnecessary complications and hinder future development. When one seeks expediency in solving a problem or implementing a feature, the failure to follow good design principles is often the cost. For issues with limited scope, this trade-off is occasionally acceptable. But as the system grows and expands, there is always a good case to be made for going back and reviewing previous design choices to analyze their scalability for the future. Failure to do so frequently leads to convoluted and unwieldy programs that are as hard to maintain as they are to be expanded upon.
